

Managing World Forests as Complex Adaptive Systems in the Face of Global Change

Prof. Christian Messier, Université du Québec à Montréal (UQAM), Research Chair in Urban Forestry, Centre d'Étude de la Forêt (CEF)

Forest management in the world today

Lindermayer et al. Cons. Letters (in press)

11%

Forest Reserves

85%

Integrated
Forest Management

4%

Intensive
Wood Production

Sensitive Areas

- riparian zones
- wetlands
- steep terrain

Management of Landscape Conditions

- spatial attributes (extent, patchiness, grain) of landscape condition (e.g. heterogeneity of forest ages at landscape scale)
- location of harvest units and roads

Management of Stands

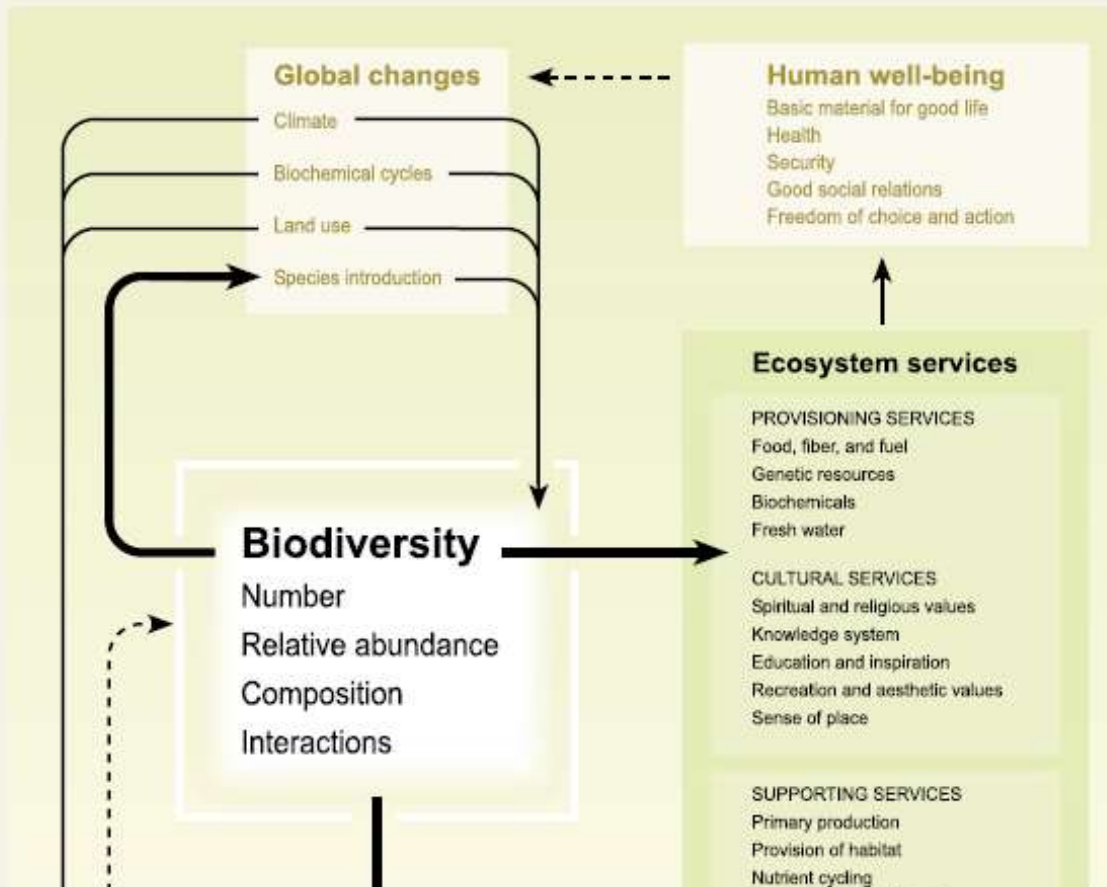

- thinning and pruning
- return interval of management
- **retention at harvest**

Forest Restoration

goal

Continuity and enrichment of structure, function and composition

Biodiversity is both a response variable affected by global change drivers and a factor modifying ecosystem processes and services and human well-being. Solid arrows indicate the links that are the focus of Chapter C11.

- ***Wood production might not be the most important reason to manage forests***

ience

Properties of Complex Adaptive Systems

Openness: Capacity of a system to exchange energy, material or information with the external environment.

Heterogeneity: Variety of the components forming the system. Can be in their nature, behaviour, spatial location, history, etc.

Hierarchy: Organization of a system that spreads over multiple levels or scales.

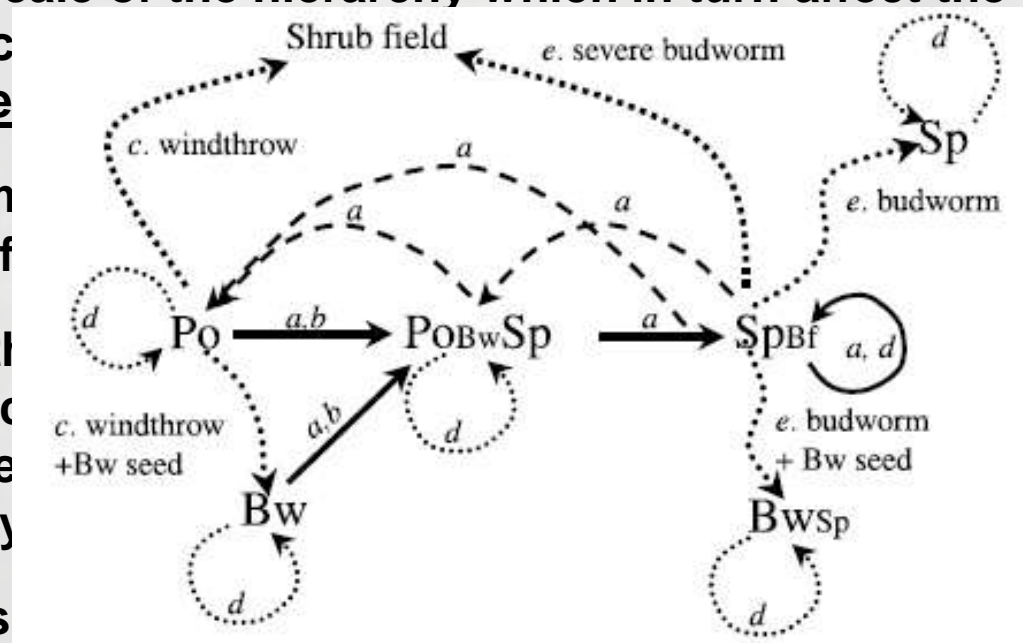

Self-organization: Process by which local interactions between components create emergent entities at a higher scale of the hierarchy which in turn affect the original components through feedback process which does not require any e

Adaptation: Ability of natural system perturbations so as to maintain their f

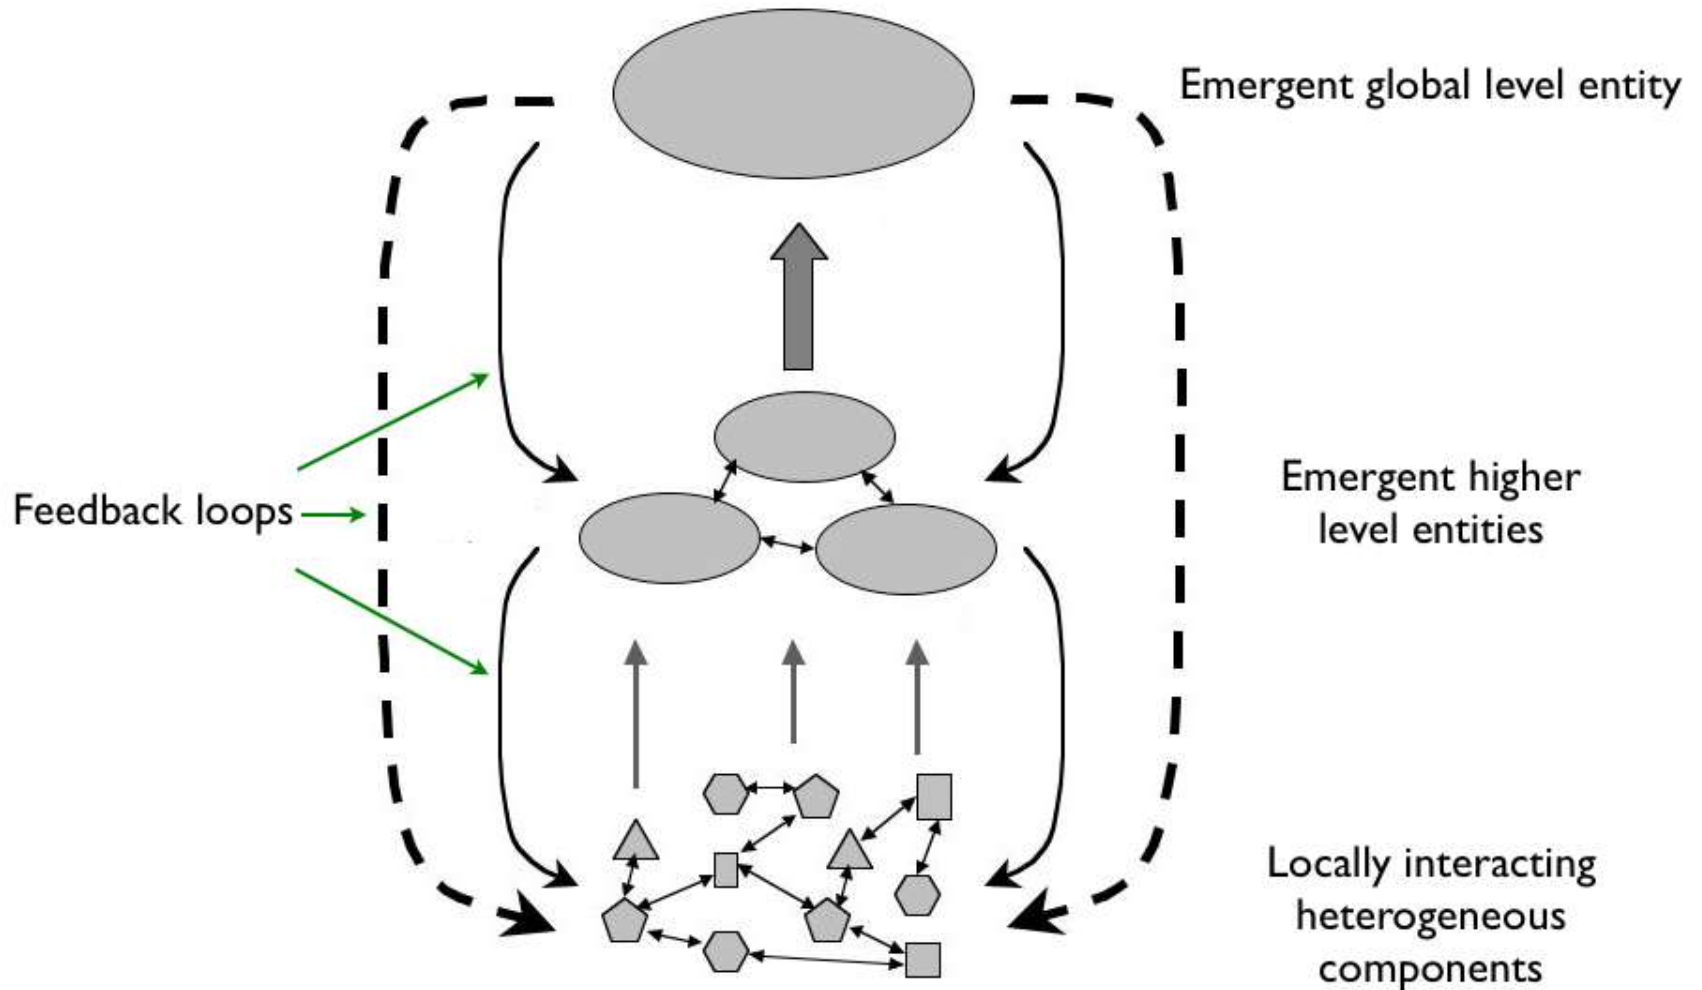

Memory: Long-lasting influence on the by the of certain behaviours or interactions higher-level entities, or external influence components or entities forming the system

Non-linearity: Characteristics of dis cause.

Uncertainty: Inability to make exact predictions about the state of the system

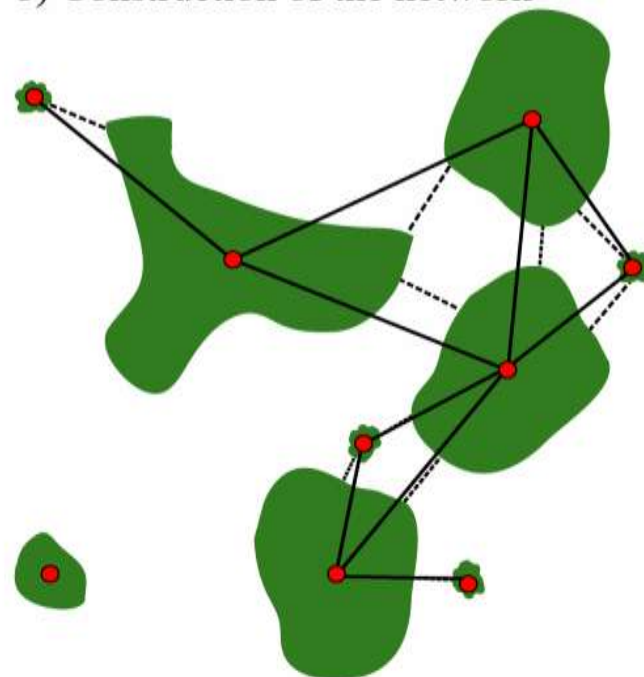

Conceptual representation of a complex system.

Diversified, complex & resilient

Complexity...
Complexity and resilience
How do we go from here?

Generalized features of *tropical forests* (shaded rectangles) are linked with attributes of **Complex Adaptive Systems** (circles).

The high resilience of tropical forest ecosystems derives from complex biotic interactions, density-dependent feedbacks, functional redundancy, and intrinsic spatial and temporal dynamics following disturbances.

ABSTRACT

Aim An important issue regarding biodiversity concerns its influence on ecosystem functioning. Experimental work has led to the proposal of mechanisms such as

Results This is the first large-scale demonstration of a strong, positive and sig-

- ***Argument against mono-culture and simplification of forests***
- ***Argument in favor of mixed plantations and more spatially and temporally diverse silvicultural practices***

More diversified plantations

- 12 indigenous species
- 7 exotic species
- Functional diversity gradient
- Mixed of 1, 2, 4 and 12 species

An overview

Regeneration burning following clearcutting in wet eucalypt forest to maintain adaptability

Variable retention in wet eucalypt forest to maintain structural and compositional heterogeneity

Management approaches that help maintain Tasmanian native forests as complex adaptive systems

1. High reservation at ***multiple scales*** via a Comprehensive, Adequate and Representative reserve network favouring ***cross-scale interactions***.
2. Regeneration burning as part of site preparation provides a seedbed for species ***adapted to natural wildfire favouring a variable and heterogeneous forest structure and composition***.
3. Herbicides, insecticides and fertilizers are not used and no subsequent tending other than occasional thinning is done following tree establishment ***allowing self-organisation to occur***.
4. Instead of planting, locally-collected seed is aerially sown. ***Genetic diversity insuring increased adaptability***.
5. Variable retention is used in place of clear-cutting in wet old-growth forests to ***maintain structural and compositional heterogeneity***.
6. Approaches to mitigating climate change impacts include seed banks, identification & protection of refugia and restoration of connectivity corridors as a way to deal with the ***increasing uncertainty caused*** by global change.

A. Biodiversity

Tree retention mitigates harvesting impacts on beetle assemblages
(Hyvarinen et al., 2009)

B. Social Acceptability

Dispersed tree retention is more socially acceptable than aggregated retention
(Ribe 2005)

C. Ecological Function

Tree retention maintains ectomycorrhiza in harvested stands
(Outerbridge and Trofymow 2009)

D. Growth & Productivity

At the same retention levels there is no difference in new cohort (seedling) productivity
(Powers et al., 2011)

E. Biodiversity

Tree retention promotes the maintenance of stingless bee populations in reduced-impact logged rainforest. (Eltz et al., 2003)

F. Biodiversity

Retention levels on logged sites affect probability of colonization by Leadbeaters Possum after only 10 years (Lindenmayer et al. 1991, 2011)

G. Economics

At the same retention levels, retention harvesting gives the same economic return as traditional shelterwood harvesting (Martinez Pastur et al., 2009)

How to measure complexity in the forest: a first attempt!

measure of ecological complexity

1440 photographs
15 forest plots from 5 forest types
3 layers (Canopy, Horizon, Understorey)

3

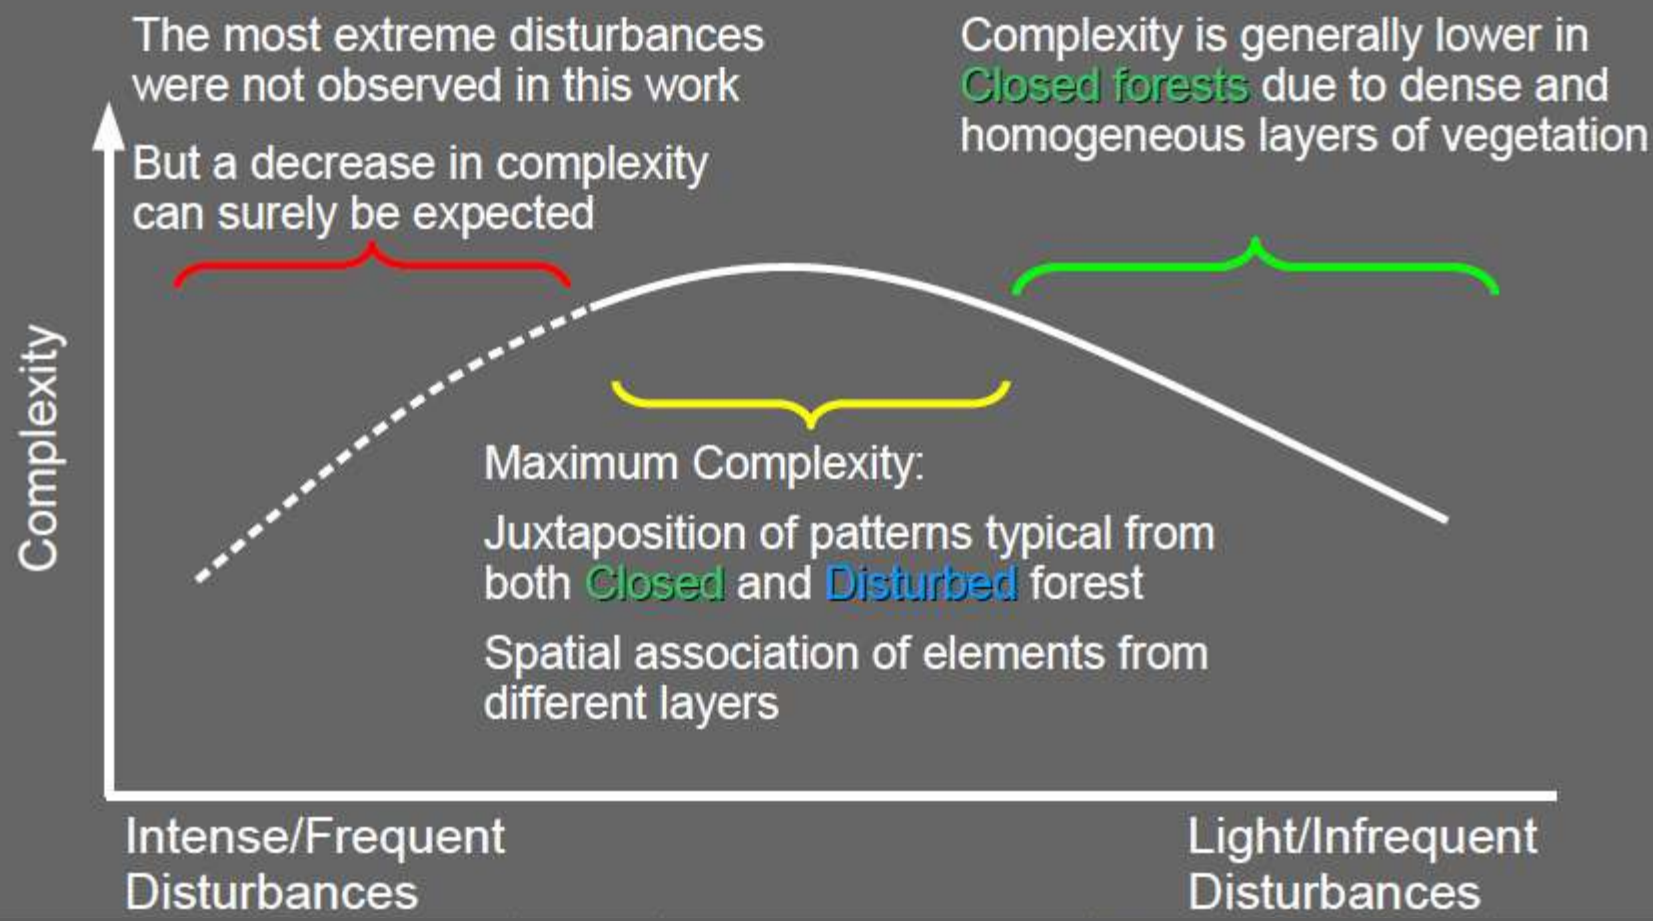

PARTIAL-CUTS INCREASE THE COMPLEXITY OF FOREST PATTERNS

Do intermediate disturbances increase complexity? Hue Patterns

3

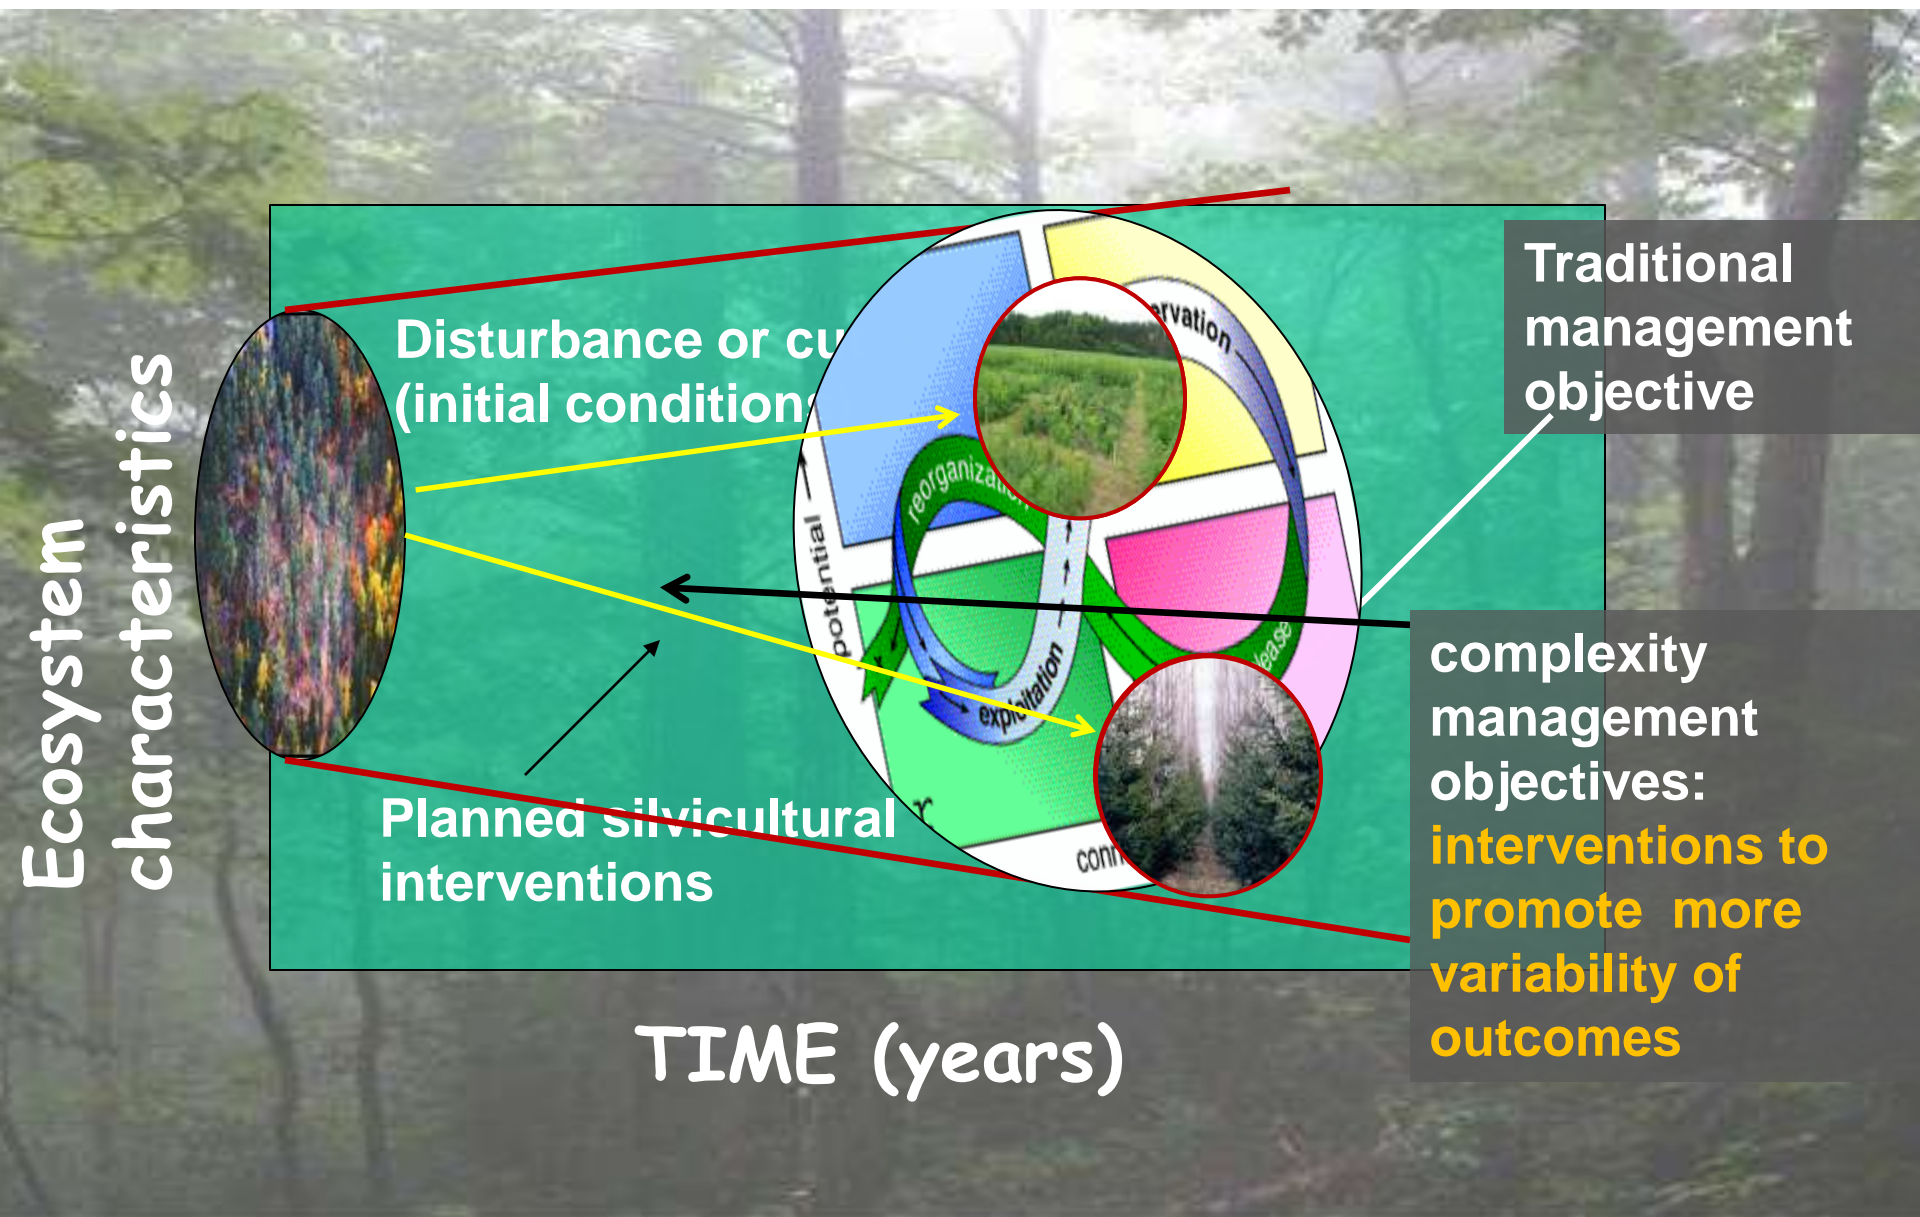

PARTIAL-CUTS INCREASE THE COMPLEXITY OF FOREST PATTERNS Do intermediate disturbances increase complexity?

Simple things that we can do

- **Facilitate and/or ASSIST tree species migration;**
- **Develop/use varied silvicultural systems that favor both functionally diverse and redundant species both spatially and temporally;**
- **Favor multi-species stands and plantations with functionally diverse and redundant tree species both within and across stands;**
- **Maintain forest connectivity across landscapes and regions**

Managing for complex adaptive systems

**Grazie/Thanks/
Merci**
